Background. Because of its physical and chemical properties, carrageenan is fairly widely used. About 70 % of the carrageenan produced in the world is used in the food industry. Previous studies point to the development of oxidative stress in rats, by means of which carrageenan chronic enterocolitis was modeled.

Objective. The aim of our study was to investigate the level of apoptosis and necrosis in the suspension of leukocytes in rats using 0.5 % and 1.0 % solutions of carrageenan.

Methods. Annexin V (V) binding assays were performed using Annexin V Apoptosis Kit (Sigma Aldrich, USA), caspase rate in leukocyte-lymphocyte blood fractions was determined by spectrofotometry.

Results. It was established that in the experimental application of carrageenan, the percentage of leukocytes with signs of apoptosis in both experimental groups statistically significantly increased. It was detected by the increased activity of effector caspase-3 in 1 month after the experiment in 1.5 times in the 2nd group and in 2.8 times in the 3rd group vs control data that point to caspase-dependent apoptotic pathway in case of carrageenan usage in rats.

Conclusions. Oral use of carrageenan in rats was accompanied by the increase in the number of leukocytes with signs of apoptosis. The animals that consumed 1.0 % solution of carrageenan had more obvious increase in the activity of caspase-3 in serum relative to a group of rats consuming 0.5 % of carrageenan, proving the increase in the severity of apoptotic processes in intestine with the increase of the dose of carrageenan.

KEY WORDS: carrageenan, apoptosis, caspase-3, rat.
activation of lipid peroxidation is caused by direct stimulation of generation of active forms of oxygen by carrageenan, or indirectly, via the tumor-alpha necrosis factor [9].

The fundamental of carrageenan influence on the body is the development of oxidative stress as one of the mechanisms of damage of intestine as well as the major multiple organ lesions in heart, lungs and liver. Therefore, the aim of our study was to investigate the level of apoptosis and necrosis in the suspension of leukocytes in rats using 0.5 % and 1.0 % solutions of carrageenan.

Methods
The study was conducted on 36 mature white nonlinear male rats, which were kept on a standard diet at the vivarium of I. Horbachevsky Ternopil State Medical University. During the study we followed the principles of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes (Strasbourg, 1986). The rats were divided into 1 control and 2 experimental groups: the 1st group – control (intact animals); the 2nd group comprised the animals that consumed 0.5 % solution of carrageenan, the 3rd group consisted of the animals that consumed 1.0 % solution of carrageenan. The 2nd and the 3rd groups of animals were provided with free access to 0.5 % solution of carrageenan and 1.0 % solution of carrageenan in drinking water for 1 month [10, 11].

Annexin V (V) binding assays were performed using Annexin V Apoptosis Kit (Sigma Aldrich, USA). Apoptotic cells of blood leukocyte suspension were identified by flow cytometry using flow cytometer Epics XL (Beckman Coulter, USA). To distinguish cells that had lost membrane integrity, propidium iodide (Pi) was added to a final concentration of 10 mg/ml before the analysis. The results were presented as a percentage of the total number of cells as follows: live cells – not stained (V/PI-), cells with early signs of apoptosis – stained with annexin (V’/PI), cells with late signs of apoptosis – positive double fluorescence staining, cells with signs of necrosis – stained with propidium iodide (V’/PI’).

To determine caspase rate in leukocyte-lymphocyte blood fractions, 0.25 ml of buffer and 50 ml of 2 mM DEVD-p-NA was added to 0.7 ml of the test liquid. It was incubated for 2 hours at 37 °C; the intensity of light absorbance was measured at 405 Nm, which was directly proportional to the product of hydrolysis of Acetyl-Asp-Glu-Val-Asp n-nitroanilide caspase – 3-n-nitroanilide [12].

Statistical analysis
The results were analyzed using Statistica 7.0 software and presented as mean with standard error of mean. The differences between all groups were determined using one-way ANOVA, followed by post hoc the Least Significant Difference test. A p-value <0.05 was considered statistically significant.

Results
It was established that with the experimental application of carrageenan, the percentage of leukocytes with signs of apoptosis in both experimental groups increased significantly (Table 1). Thus, the percentage of V’/PI- cells in the 2nd group increased in 1.9 times, and in group 3 – in 2.2 times vs the control indexes (p<0.001). The percentage of leukocytes with later signs of apoptosis increased significantly, with respect to control: in group 2 – in 8.9 times, in group 3 – in 22.3 times (p<0.001). It should be noted that the level of necrotic cells when introducing 0.5 % carrageenan did not significantly differ from the normal indices, while the use of 1.0 % solution of carrageenan in drinking water caused the increase of V’/PI’-cell in 1.7 times (p<0.001).

Caspases in general are important mediators in apoptosis, especially caspase-3, which is the main caspase effector that cleaves cell substrates. It was established that the activity of caspase-3 effector in 1 month of the experiment increased in 1.5 times in the 2nd group and in 2.8 times in the 3rd group vs control data that proved the caspase-dependent apoptotic pathway in case of carrageenan use for rats (Fig. 1).

Discussion
Caspase-3 is probably the best understood of the mammalian caspases in terms of its specificity and roles in apoptosis. Overall, recent progress has generally confirmed the notion of multiple, complex death pathways (some of which require caspase-3 in specific cell types) that converge on common events including cell shrinkage, blebbing, chromatin condensation and DNA. Two established ways of apoptosis include internal or mitochondrial, involving protein family Bcl–2, cytochrome С and caspase – 9 and external with the activation of caspase–8 linking a specific cell receptor Fas– and soluble tumor necrosis factor receptors on the cell
surface [13]. Caspase-3 is the most involved pathway which should be generated from its inactive protein (procaspase-3), caspase 3 is required for some apoptosis features (chromatin condensation, DNA damage and apoptotic body formation) and its part may take place before cell viability suppression starts [14]. Hridneva SV notes that in chronic enterocolitis endothelial functions are impaired, which manifests itself in the activation of free radical oxidation processes with underlying decrease in the activity of the antioxidant system that explains the excessive production of ROS [15] and cell death. The activity of caspase-3 increases with increased carrageenan concentration, that proves a more obvious enterocyte apoptosis with the increase in daily intake of carrageenan. At the same time, animals of the 3rd group have a more obvious increase in the activity of caspase-3 in serum, indicating the increase in the severity of apoptotic processes in intestine. The obtained data contradicts the results of some studies that prove that exposure of human intestinal epithelial cells to carrageenan in vitro does not lead to the activation of caspase-3, caspase-7 or increased percentage of fragmented DNA, suggesting no apoptotic alterations following carrageenan exposure [16]. Otherwise, the results of other studies evidence that carrageenan induced chronic gastroenterocolitis is accompanied by the decrease in the activity of PARP and elevation of MMP-2, MMP-9 and caspase-3 in blood serum of animals [17]. The results are controversial and require detailed consideration. Therefore, further research is warranted to elucidate the role of carrageenan in intestinal caspase-depending cell death that

may help define novel nutritional strategies for hindering the development of gut diseases.

**Conclusions**

Oral use of carrageenan in rats was accompanied by the increase of the number of leukocytes with signs of apoptosis: V+/PI- cells in the 2nd group increased in 1.9 times, and in the 3rd group – in 2.2 times, V+/PI+ cells increased in 8.9 and 22.3 times, compared with the control (p<0.001); the percentage of leukocytes with later signs of apoptosis was significantly increased too (p<0.001).

Animals that consumed 1.0 % solution of carrageenan had more obvious increase in the activity of caspase-3 in serum relative to the group of rats consuming 0.5 % carrageenan, proving the increase in the severity of apoptotic processes in intestine with the increase in the dose of carrageenan.
